INTERNATIONAL FOOD POLICY RESEARCH INSTITUTE

The International Food Policy Research Institute (IFPRI), established in 1975, provides research-based policy solutions to sustainably reduce poverty and end hunger and malnutrition. IFPRI’s strategic research aims to foster a climate-resilient and sustainable food supply; promote healthy diets and nutrition for all; build inclusive and efficient markets, trade systems, and food industries; transform agricultural and rural economies; and strengthen institutions and governance. Gender is integrated in all the Institute’s work. Partnerships, communications, capacity strengthening, and data and knowledge management are essential components to translate IFPRI’s research from action to impact. The Institute’s regional and country programs play a critical role in responding to demand for food policy research and in delivering holistic support for country-led development. IFPRI collaborates with partners around the world.

Abstract

There is very limited experimental evidence of the impact of large-scale, government-led school meals programs on child educational achievements in Sub-Saharan Africa. We address this gap by reporting treatment effects from a nationwide randomized trial of the Government of Ghana’s school feeding program (GSFP) on children’s math and literacy, cognition (problem-solving ability and working memory), and composite scores of overall attainments. Based on the government’s plans to re-target and scale up the GSFP, food insecure schools and related communities across the country were randomly assigned to school feeding. After two years of implementation, program availability led to moderate increases in test scores for the average pupil in school catchment areas, ranging between 0.12 and 0.16 standard deviations. Analysis focusing on per-protocol population subgroups unveiled substantial heterogeneity: school feeding led to remarkable learning and cognitive gains for girls, poorest children, and children from the northern regions. Program effects were at least twice as large as for the average child. Increases in enrolment, grade attainment, and shifts in time use toward schooling time constituted potential mechanisms for impact. We conclude the program combined social protection with equitable human capital accumulation, thus contributing to the imperative of “learning for all” set in the Sustainable Development Goals.

Acknowledgments

The trial has received IRB approval from the University of Ghana. This study is registered in the AEA RCT Registry and the unique identifying number is AEARCTR-0003629. The trial is also registered in the ISRCTN registry with the following identifying number ISRCTN66918874.

The authors gratefully acknowledge the enabling environment provided by the Government of Ghana, particularly the Ghana School Feeding Programme (GSFP), for supporting the trial. Specific individuals include GSFP national coordinator, Hon Siedu; and Paakuna Adamu and his team, including Mrs Kuma Mintah, Mrs Anima Wilson, Mrs Susan Torson, and Mr Kwame Nuako, as well as regional and monitoring coordinators and district desk officers, who also provided significant support. The authors also thank Prof Lesley Drake at the Partnership for Child Development (PCD) for her critical role in making the trial possible; they recognize the key role played by PCD staff and associates in London and Ghana, in particular, Don Bundy, Daniel Mumuni, and Josephine Kamba, Getrude Ananse-Baiden, Lutuf Abdul-Rahman, Rosanna Agble, Abigail Bondzie, and Fred Amese. Also, they thank Felix Asante, Kwabena M. Bosompem, Gloria Folson, Anthoni Kusi, Daniel K. Arhinful, and Irene Ayi at the University of Ghana. We also wish to thank Pedro Rosa Dias, Jan Ross, Franco Sassi, Jacob De Hoop and participants at seminars at IPA Conference on Education (Ghana), Italian Conference of Public Economics, and UNICEF Innocenti for helpful comments.

The authors acknowledge funding from the Bill and Melinda Gates Foundation, the World Bank, and Dubai Cares. Elisabetta Aurino gratefully acknowledges the financial support of the Imperial College Research and Guido Cazzavillan Research Fellowships and the hospitality of Prof Felix Asante and his team at ISSER/University of Ghana during initial analyses.
1 Introduction

Average learning levels for primary school pupils in low- and middle-income countries (LMICs) are dismal: for instance, only 40 percent of students in Sub-Saharan Africa (SSA) master basic literacy and numeracy at the end of primary school (World Bank 2018). Further, large inequalities in achievements are present, with children from lower socioeconomic status or rural households, and, sometimes girls, lagging behind the average pupil. This "learning crisis" occurred despite unprecedented expansion in primary school access and completion: in SSA, for example, 78 percent of children at primary school age were enrolled in 2014, up from 58 percent in 1999 (World Bank 2017). A critical question for policy is therefore how to raise average achievements and narrowing learning gaps for marginalized students, coherently with the principle of "quality education for all" underscored by the Sustainable Development Goal 4 (SDG4).

Currently, there is very limited rigorous evidence focusing on the effectiveness of large-scale, government-led interventions on human capital, especially in SSA. One of such interventions is school feeding, which ranks amongst the world’s most common forms of social protection. Every day, about 368 million children receive some form of school feeding globally, for an estimated investment of $70 billion a year (Honorati, Gentilini, and Yemtsov 2015; WFP 2013). In SSA, since the early 2000s, a large number of countries have invested in school feeding as a multisectoral strategy involving education, health, and agriculture (Alderman and Bundy 2012; Drake et al. 2017). However, these programs can be relatively expensive to operate: at an average cost of US$54 and US$83 per child per year in low- and middle-income countries, respectively, and often with limited poverty targeting, the share of the educational budgets devoted to school feeding is considerable (Gelli and Daryanani 2013). Thus, quantifying the impact of school feeding on human capital is critical for policy makers in resource-constrained settings evaluating intervention options to attain SDG4.

School feeding has a robust track record in increasing school participation (Alderman and Bundy 2012; Drake et al. 2017; Kristjansson et al. 2015). Yet, experimental evidence on the
effectiveness of school feeding on educational achievements is more limited, and with mixed findings (see Appendix A and Snistveit et al. [2015] for a meta-analysis). Of importance, in Africa and elsewhere, experiments have evaluated programs implemented as part of international food aid, usually by the World Food Programme (WFP) or other international NGOs, at a relatively limited scale (Alderman, Gilligan, and Lehrer 2012; Kazianga, de Walque, and Alderman 2012, 2014; Neumann et al. 2007; Omwami, Neumann, and Bwibo 2011; Powell et al. 1998; van Stuijvenberg et al. 1999; Vermeersch and Kremer 2005). In these studies, school feeding was usually undertaken in restricted geographic contexts during limited time periods between baseline and follow-up, and programs often employed complex or unsustainable supply chain logistics (e.g., menus including perishable and/or higher-cost foods).

Government programs reaching daily large populations may suffer from a number of additional challenges as compared to smaller-scale interventions implemented by international NGOs, including market equilibrium effects and spillovers (Acemoglu 2010; Cunha, De Giorgi, and Jayachandran 2018; Filmer et al. 2018); endogenous political economy reactions (Bold et al. 2018); heterogeneity by site or implementer characteristics (Allcott and Mullainathan 2012); and implementation challenges related to scale, including poor monitoring (Linnemayr and Alderman 2011). These issues may all hamper the generalizability of evidence based on smaller-scale, internally-valid trials to “real-world” programs reaching large populations (Banerjee et al. 2016; Bold et al. 2018; Deaton and Cartwright 2018; Nandi et al. 2017; Pritchett and Sandefur 2015). Also, existing literature has seldom analyzed mechanisms underpinning treatment effects, which are instead critical to assess external validity. Analysis of heterogeneity in treatment effects between average and marginalized learner groups constitutes a further key evidence gap (Bashir et al. 2018; Evans and Yuan 2018).

We tackle these gaps by providing novel experimental evidence on the impact of the Ghana School Feeding Programme (GSFP) on child educational achievements. The GSFP provides a free, hot-cooked daily meal to over 2 million pupils in government primary schools across Ghana. In collaboration with the Government of Ghana, we conducted a randomized control trial around the re-targeting and scale-up of the GSFP to the country’s most food insecure districts,
which were previously not covered by the program. While the overall trial aimed at assessing program impacts on education, nutrition, and agriculture (see Gelli et al., 2016), here we report treatment effects on per-protocol educational attainments outcomes, including child learning (maths, literacy), cognition (working memory, problem-solving ability), and overall achievements. We also assess treatment effects mechanisms and heterogeneity by per-protocol population subgroups.

Ghana represents an ideal context to study the learning effects of government school meals programs. The country faces similar challenges to other LMICs with regards to both low learning and program implementation at scale. First, while the country’s efforts to raise schooling in the 2000s resulted in primary enrolment rates that are among the highest in SSA, average learning levels are low: a 2017 study highlighted that more than 80 percent and 70 percent of Grade 2 and Grade 4 students, respectively, could not read a single familiar word or perform a two-digit subtraction (World Bank 2018). Second, wide inequalities in achievements exist by gender, poverty, and place of residence (World Bank 2018). Third, despite rapid economic growth, food insecurity and poverty are widespread, particularly in rural areas. In this context, school feeding programs, through targeting the transfer directly at the child conditional on school attendance, may be more effective in raising learning through lowering educational costs, including the opportunity cost of schooling, than alternative social protection measures that target households, such as cash transfers or generalized food assistance (Aurino et al. 2018). This mechanism could be particularly pronounced among the most vulnerable groups of learners. Further, Ghana is highly varied in terms of agroecology, ethnicity, socioeconomics, as well as political and administrative capacities. Uncovering the average effect of the program, in face of this diversity and potential heterogeneous program implementation and monitoring across regions is therefore of interest for policy makers operating in similar settings.

Following the methodology outlined in our study protocol (Gelli et al. 2016), we document the following intent-to-treat (ITT) findings. After almost two academic years of implementation,
exposure to school feeding led to increases in all scores considered by about 0.1 to 0.16 standard deviations ($\partial$, hereafter) for the average pupil. We note that these findings are likely to correspond to lower bounds of potential effects, as program take-up was imperfect and implementation challenges were present. The latter mostly related to severe delays in financial disbursements to the caterers, which are in charge of procuring food, and cooking and serving the meals.

Turning to heterogeneity, we find strong variation in program impact in favor of the most marginalized groups of learners. Girls’ maths, literacy, and learning composite scores increased by $0.2\partial$ in school feeding communities. Treatment effects among children living in the northern regions, the country’s most disadvantaged areas, and for children from households below the poverty line at baseline ranged between $0.25\partial$ and $0.3\partial$ across all scores.

The offer of school feeding led to increases in school enrolment, grade attainment, and, for poorest children, shifts in child time use from housework toward increased time in school, which we interpret as likely impact pathways. Overall, these results underscore the social protection-cum-human capital accumulation of a large-scale, government-led school feeding program, which appeared particularly effective in raising learning outcomes of the most vulnerable learner subgroups in Ghana.

We believe that this paper contributes to the literature in multiple ways. To the best of our knowledge, this is the first field experiment from Africa investigating the effects of a government-led nationwide program on a rich set of educational attainments. Therefore, it adds to a literature that, as noted, is overwhelmingly focused on smaller-scale trials based on programs financed and implemented by international actors. The magnitude of the average effects are similar to a quasi-experimental study focusing on the Indian school meals program, a government-run intervention implemented at massive scale (Chakraborty and Jayaraman 2016), as well as to results emerging from a meta-analysis of different trials and quasi-experimental studies (Snilstveit et al. 2015). Additionally, we provide evidence on treatment effects heterogeneity for the most marginalized learners, which is, surprisingly, an under-investigated topic in educational research in LMICs (Bashir et al. 2018; Evans and Yuan 2018; World Bank 2018). Our findings suggest that in contexts characterized by wide educational inequalities such
as Ghana, school feeding programs may be able to “level the playing field” by raising learning outcomes, especially among children at the margin (Jukes, Drake, and Bundy 2008).

More broadly, this study speaks to a body of literature employing randomized trials to evaluate the learning and cognitive impacts of educational, health, and social protection interventions, particularly in SSA (Evans and Popova 2015; Glewwe and Muralidharan 2016; De Groot et al. 2015). In the case of social protection, existing evidence is overwhelmingly focused on schooling (enrolment and attendance), rather than on learning achievements (Baird et al. 2014; De Groot et al. 2015).

This paper is organized as follows. The next section presents the background and the study design. Then, Section 3 illustrates the data and identification strategy. Sections 4 and 5, respectively, present the ITT estimates and potential mechanisms for impact. Section 6 presents some cost considerations, while concluding remarks are offered in Section 7.

2 Background and Study Design

2.1 School feeding and child learning: potential pathways for impact

Improved school participation, changes in time use, and enhanced health and nutrition constitute potential channels through which school feeding can affect learning (Adelman, Gilligan, and Lehrer 2009). First, school meals may have an incentive effect on enrolment and attendance by subsidising the cost of education through the provision of a free meal conditional on attendance, which may contribute to shifting household decisions toward increased schooling. In turn, increased attendance may have a positive effect on learning. Also, the school feeding transfer may free up resources that households could use to purchase additional educational inputs for improved child learning, such as books, other educational materials, or private tuition.

Second, beyond fostering attendance through subsidising the costs of education, school feeding may contribute to changing children’s time use through a shift from labor (particularly in agriculture) toward increased time devoted to educational activities (Alderman, Gilligan, and Lehrer 2012; Kazianga, De Walque, and Alderman 2009). A meta-analysis has shown that
increases in time spent at school may be an important pathway to better learning achievements (Snilstveit et al. 2015).

Also, by addressing short-term hunger and micronutrient deficiencies, including iron and iodine, school feeding can positively affect children’s learning and cognition via reduced morbidity-related absenteeism, better micronutrient status, and increased concentration in the classroom. It may be plausible that teachers can be more motivated by interacting with more responsive pupils (Afridi, Barooah, and Somanathan 2013; Glewwe and Kremer 2006). The potential health impacts of school feeding may be offset by substitution between meals, or changes in the intrahousehold distribution of food, as this could be diverted away from the child receiving the free meal, though evidence of this effect is inconclusive (Ahmed 2004; Chakraborty and Jayaraman 2016; Jacoby 2002; Kazianga et al. 2014). Also, high heterogeneity in the health pathway may be present, with effects mostly concentrated among malnourished children (Krämer, Kumar, and Vollmer 2018; Powell et al. 1998).

Investments in children’s education, and related academic attainments, can vary by child and household characteristics (e.g., uneducated parents, poorest or remote households, etc.), and by school quality (e.g., teachers availability and experience, educational supplies, and facilities, etc.). It may be the case that marginalized learner groups such as girls, lower-ability children, and children from economically-disadvantaged households and areas may benefit disproportionately more from the transfer in terms of human capital investments than less disadvantaged pupils (Akresh, De Walque, and Kazianga 2013; Björkman-Nyqvist 2013).

2.2 Basic education in Ghana

Ghana’s basic education is compulsory between 5 and 15 years. During the 2000s, the country prioritised school participation through various initiatives, including the establishment of the GSFP in 2005. These efforts resulted in a substantial expansion of basic education, with primary enrolment moving from 61 percent in 1999 to 87 percent in 2016 (World Bank 2017). Despite these impressive achievements, an estimated 300,000 to 800,000 children are still out of primary school, mostly from households below the poverty line and from the country’s northern regions (UNDP Ghana 2015). Moreover, Ghana’s success in expanding schooling has not been
matched by corresponding improvements in learning, which remain overwhelmingly low as compared to international standards (Ministry of Education/RTI International 2014). As per educational access, wide inequalities in achievements exist by gender, poverty, and northern regions (World Bank 2018).

### 2.3 Ghana School Feeding Programme

The GSFP is funded by the Government of Ghana with a 4-year program budget of over US$200 million (GSFP 2006). GSFP coordination and implementation are undertaken by a National Secretariat, with program oversight provided by the Ministry of Gender, Children and Social Protection. Funding for the program is now integrated to the government annual budget. The program is decentralized; private caterers are awarded contracts by the GSFP to procure, prepare, and serve food to pupils in the targeted schools. Cash transfers (and, recently, electronic payments) are made from the District Assemblies to caterers based on 54 Ghana pesewas per child per day (circa US$0.33) every two weeks. Each caterer is responsible for procuring food from the market on a competitive basis, preparing school meals and distributing food to pupils. Supervision at the school level is undertaken by the School Implementing Committees. Delayed reimbursements to caterers are common, with delays as long as half a year or even a whole year (SEND-Ghana 2013). Delayed payments to caterers often result in caterers reducing the quantity or quality of food provided, or adjusting the school feeding menus, thus likely influencing program quality, and potentially, effectiveness (Ghana Institute of Management and Public Administration 2011).

### 2.4 Evaluation design

The trial was designed around the scale-up of the GSPF to new intervention districts, based on the 2012 retargeting exercise. The retargeting was guided by the development of poverty and food insecurity rankings to assess potential priority districts in which the GSFP could be rolled-out (See Appendix B for details). Rankings were used to generate district-level indices on the share of national poverty and food insecurity, through which 58 priority districts were
identified for the scale-up of GSFP.

The trial focused on assessing program effects on both child-level (education, health) and district-level agriculture. In order to affect these different sets of outcomes, program components were delivered at different administrative levels: the school feeding service (which was hypothesised to affect mostly child education and health) was designed to be delivered at the school-level, while the agriculture-related activities were delivered at the district-level, also affecting communities that would not offer school feeding. A complex study design was therefore required, which was achieved through a multiple-level randomization (Figure 1). First, districts identified from the retargeting exercise were randomly assigned to two treatment arms: the standard GSFP and a “home-grown” school feeding (HGSF) pilot including an integrated package of activities aimed at enhancing the impact of the GSFP on community agriculture and food security (Gelli et al. 2016). At the second stage, two schools (and relative school-catchment areas, which we refer to as “communities” therein) were randomly assigned within each district to a school feeding or control arm. Control schools and communities were planned to receive school feeding at the end of the trial. A protocol was designed in order to ensure that the sampled schools were comparable based on Education Management Information System (EMIS) data (for details, see Gelli et al. [2016]). Following a household census at baseline, approximately twenty-five households with children in the 5-15 target-age group were randomly selected for interview from each community.

The multi-level design compared the child-level outcomes (e.g., education, health) between children belonging to school feeding (including both GSFP and HGSF modalities) and control communities, and the agriculture impacts of the HGSF pilot relative to the regular GSFP at district-level. This paper focuses on the impact on child educational achievements, and the results of the analyses on child anthropometrics and community agriculture will be published separately, as per analysis plan.

[FIGURE 1 ABOUT HERE]

---

3 The original design had actually a three-level randomization, with a subset of HGSF schools receiving micronutrients constituting a fourth study arm (Gelli et al. 2016). However, the discovery of existing GSFP in 25 schools of the original sample after the baseline survey and their consequent exclusion from the sample led to the removal of the fourth study arm due to loss of power. This decision was also based on substantial delays in delivering micronutrient powders to the schools that were supposed to receive them, which were core to identifying differences in the third randomisation level.
3 Data and Sample Description

3.1 Timeline and Sample

A baseline survey was undertaken in 93 communities between June and September 2013. The sample included 1,838 households with children of target-age for the intervention. The follow-up survey was conducted in February-March 2016. The program started in the academic year 2014/15, due to bureaucratic delays. Given that the academic year in Ghana usually runs from August to May, the program was evaluated after roughly two academic years of implementation.

Two communities were excluded from the endline survey, due to logistical problems related to episodes of local insecurity. Both rounds of household surveys included detailed modules on household demographics, farm and other assets, expenditures, farming and other economic activities, child anthropometry, and self-reported education indicators for all target-age children in the household, including child enrolment, attendance and grade attainment, and educational achievements. At endline, data on children’s time use were also collected. Of the 4,269 target-age children sampled in 2013, 836 were in the last year of primary school or had already completed primary school. As such, they were not eligible to receive the GSFP intervention when implementation began and were therefore excluded. At endline, we successfully reinterviewed 92 percent of children of target-age and eligible to receive school feeding, leading to a longitudinal sample of 3,170 children.

3.2 Balance of Baseline Covariates and Attrition at Endline

Table 1 presents descriptive statistics of baseline characteristics of the longitudinal sample by treatment arm. The average child was about 8.5 years old, with children from the school feeding arm on average a month older than control. Almost all children were enrolled in school at baseline, and a tenth of them attended private schools. The average child had completed less than two years of schooling, and about 11 percent had repeated a grade. Along

---

4 In the case of young children, the caregiver reported on schooling.
with the descriptive statistics, we present a balance test to assess whether the randomization was successful in achieving balance of baseline covariates. The only difference between the two groups that was statistically significant at 10 percent was age of household heads in the school feeding arm, which were about one-year-and-a-half older than control communities. A similar picture emerged from the balance analysis focusing only on the baseline sample prior to attrition (Appendix C). These findings, together with the relatively small size of the differences, suggests that the randomization was overall successful in achieving balance.

**[TABLE 1 ABOUT HERE]**

Table 2 presents attrition tests at the child level. We do not observe any unbalance in the probability of remaining in the longitudinal sample based on offer of school feeding, which would have otherwise introduced some bias in the estimation of the treatment effects, affecting internal validity\(^5\). Column 2 presents analysis of whether baseline test scores were associated with children being more likely to be resurveyed, which did not appear to be the case either. Finally, column 3 investigates whether the treatment was associated with some child characteristics in predicting odds of remaining in the sample, which may introduce some sample composition bias. We did so by interacting the treatment with some of the key characteristics we use for heterogeneity analysis throughout the paper. We find these interactions were jointly significant at the 5 percent level, mostly due to the fact that children in control areas in northern regions were slightly more likely to be reinterviewed at endline (96 percent of baseline children were followed up in control communities, viz. 93 percent in treatment areas, translating in, respectively, for a total of 36 additional children lost in treatment areas compared to control). To evaluate further the possible effects of attrition on validity of the impact estimates, Appendix D presents the balance of characteristics across treatment groups at endline for the full sample, and for the northern regions only. Across a wide range of child and household backgrounds, there were no differences between school feeding and control arms for the longitudinal sample at endline. Thus, even if there was some evidence of differential attrition by treatment in the case of northern regions, balance was generally maintained, particularly in light of the relatively low levels of attrition overall and especially in the northern regions, lessening concerns of a change

\(^5\) This result did not change when we split treatment in GSFP and HGSF pilots (available upon request).
in the sampling frame by treatment assignment due to attrition.

3.3 Program Uptake and Implementation

Only 61 percent of children in school feeding areas reported receiving school meals in the previous week at endline, which we refer to as the overall uptake rate. By restricting the sample of children that were enrolled in primary government schools (as opposed to private schools) in treatment communities, the uptake rate was 83 percent, indicating that most children that were still in basic education did in fact receive school meals. We remind that school meals are not served in secondary schools.

Appendix E presents correlates of endline uptake (independent of primary enrolment status) among children in treatment communities. Coherently with expectations of older children having progressed to secondary school or being out of school at endline and thus being less likely to receive school feeding, children aged 5-11 years at baseline were two times more likely to receive school feeding compared to adolescents (12-15 years at baseline). There was no gender variation in the odds of uptake, while household poverty at baseline and northern regions were predictive of about 2 times higher chances of reporting school meals receipt. Baseline maths and literacy scores were associated with lower odds of school feeding. This finding may be due to faster progression to secondary school for pupils that had higher achievements at baseline. The type of program to which a child was assigned (e.g., standard GSFP viz. HGSF pilot) was not predictive of uptake, which reassures about potential concerns of implementation variation between the two school feeding modalities.

Fewer than 2 percent of children in control areas were found to have received school feeding at endline, ruling out the possibility of significant crossover, which would have hampered the experimental design.

Eighty percent of children that reported receiving school feeding in the treatment arm at endline ate at school during all days in the previous week, suggesting a fairly regular service provision. Twenty-three percent of children in the treatment group reported they were more likely to eat less food at home on days they eat at school, indicating some substitution between
meals. However, only four percent reported to bring to bring their food from the school meal to share at home. There were no differences between treatment and control groups in the mean number of school-days in which the child had breakfast (four out of five days)\(^6\).

Data collected from school caterers (N=55) highlighted that 86 percent of them experienced irregular payments, and about a third of them had not received any payment in the three months before the survey. No regional differences were evident. Nearly 85 percent of caterers also indicated that often payments are insufficient to cover operational costs, which led them to recur to credit to avoid changing the content and size of meals (83 percent), cutting on portion sizes (9 percent), or adopting a mix of other strategies to reduce costs (e.g. reduce personnel).

### 3.4 Measures of Child Learning and Cognition

Child maths, literacy, and cognitive test scores are the primary study outcomes per protocol (Gelli et al. 2016). The same 15-item maths and literacy tests, and 12-item SPM and digit span tests were administered across rounds for comparability. Tests were administered at home to ensure that even children out of school were tested, enhancing internal validity. Given the wide age range included in the target sample, the tests aimed to assess a basic set of skills in literacy, maths, and in cognitive development domains. Each section of the test began with basic domain-specific questions that progressively increased in difficulty in order to cover different ability levels, particularly in the light of the diverse age range of eligible children. The maths assessment included questions on recognition of single or double-digit numbers, basic arithmetics, fractions, and basic problems (e.g., how many minutes/hours in 120 minutes), while the literacy test assessed letter recognition, reading short words and sentences, and three final questions on completing a sentence with the correct item among four possible choices. The standardized progressive matrices test (SPM) test was an adaptation of the Raven’s progressive matrices test, a commonly-used measure of nonverbal fluid intelligence and problem-solving ability, while the digit span test focuses on assessing working memory. For each question of the SPM test, the child

---

\(^6\) Fernandes et al (2017) reports detailed findings from focus groups on children’s dietary behaviors in the context of this evaluation. Also, a companion paper related to impact findings on nutrition will explore these issues in more depth.
was given a set of images, and was asked to choose the image that would complete the picture. For the digit span test, the child was presented sequences of numbers of increasing lengths, and was asked to recall the sequences as prompted (forwards) and reversing the number order (backwards).

Test scores were standardised by child age in months for each survey round, with the control group having mean 0 and standard deviation 1, in order to deal with the wide age groups assessed as part of the evaluation. In line with the literature (e.g., Banerjee et al. [2007] and Das et al. [2013]), this was achieved first by removing interviewer effects from the raw scores through a OLS regression on interviewer dummies. Later, the residuals from these regressions were non-parametrically estimated to obtain age-conditional means and standard deviations.

We also generated composite indicators of learning, cognition and across all the outcomes considered to address potential issues related to multiple testing. The summary indices should enhance statistical power to detect effects that go in the same direction (Kling, Liebman, and Katz 2006). We computed those as an average from the normalized test scores, and then standardized again to the control group within each round. In this way, estimated ITT effects can be interpreted as the effect size relative to the control group (Banerjee et al. 2015).

3.5 Descriptive Statistics of Learning and Cognition

Table 3 presents descriptive statistics of raw tests scores in the four competencies by intervention arm for the longitudinal sample. School feeding children had larger scores in both rounds, with the difference from control being more pronounced at endline. However, none of

---

7 This approach also helped controlling for potential language effects, as unfortunately we do not have information on the specific language of administration of the test, as each interviewer spoke a different local language.

8 This was not included in our original analysis plan. However, this is a common approach in the literature to create more general conclusions about the impact of a program on a family of outcomes (Banerjee et al. 2007; Kling, Liebman, and Katz 2006; Wydick et al. 2016). Wydick et al. (2016) note that this approach “help addressing the issue of over-testing that could erroneously assign too much importance to a possibly spurious rejection of a single null hypothesis for one variable within a family of outcomes” (p. 18).

9 Although children were given assessments in all tests, discrepancies in sample sizes across raw and standardised scores reflect inability to convert raw scores into standardized scores (e.g. lack of child age in months). A similar issue is highlighted in (Graff Zivin, Hsiang, and Neidell 2018) This could be a potential concern if the missing scores correlate with treatment assignment. Regressions of treatment on score availability rules out this hypothesis, as the coefficients are zero and not statistically significant across all outcomes (result available upon request).
the differences prior to the beginning of the intervention appeared to be statistically distinguishable from zero\(^{10}\).

The analysis of the raw scores highlights the low achievement levels in each outcome and survey round: at baseline, on average, children were not able to respond to at least two out of 15 questions in the Maths and Literacy tests. This proportion increased slightly three years later. However, endline scores were still very low, with the average pupil only being able to respond to about 4 out of 15 correct questions for maths and literacy, which reflects Ghana’s learning challenge.

By contrast, the mean levels of Digit Span achievements did not change over time, and for SPM they decreased between baseline and endline. This decline was common across all groups, but was wider in the case of the oldest children that were not enrolled at endline (12-15 years at baseline). This may suggest some deterioration of cognitive skills after school leaving, such as recently reported by Soler-Hampesjsek and coauthors (2018).

\[\text{TABLE 3 ABOUT HERE}\]

Appendix F presents raw scores at both rounds by child gender, household poverty status and by residence (south vs. north Ghana). At both rounds, there were no strong differences between girls and boys, while gaps between nonpoor and poor children were evident across all outcomes. The largest disparities in baseline achievements, however, were between northern and southern regions, underscoring important geographic inequalities. Children from the southern regions had, on average, responded to about one additional question than northern children across all competences. This gap substantially reduced or closed at endline.

Figure 2 presents the non-parametric distributions of raw scores in maths and literacy at both rounds by treatment arm. There were important floor effects for low levels of achievements in both maths and literacy, whereby a significant proportion of children did not respond correctly to any question, indicating the tests were too difficult for them. This was especially marked among younger children at baseline. A basic reading assessment in Ghana reported similar floor effects, whereby 42 percent and 20 percent of Grade 3 and Grade 6 students, respectively, did

\(^{10}\) A similar picture emerged from the analysis of baseline differences in raw scores for the baseline sample prior to attrition presented in Supplementary Table A1. This provides a further reassurance about potential biases in treatment effects of school feeding on child learning stemming from nonrandom attrition.
not respond correctly to any of the test’s six questions (Balwanz and Darvas 2013). Given the relatively-low proportion of children that were able to respond correctly to all questions, ceiling effects were not a concern. Also, there was an increase in the variance of learning achievements between baseline and endline. This may reflect widening of educational inequalities in the transition from primary to higher levels of education. At the end of primary school, the most vulnerable children tend to enter the labor market, thus widening pre-existing educational disparities (De Groot et al. 2015). The distribution of achievements of the school feeding group appeared to be above the one of control at endline across the mid- to upper-end of the distribution of both maths and literacy. The marked gains for above-average levels of achievements among the school feeding group at endline is clearly observable in Supplementary Figure G1, which plots age-standardized empirical distributions of maths and literacy by treatment arm and round.

[FIGURE 2 ABOUT HERE]

Figure 3 presents the non-parametric distributions of raw test scores in Digit Span and SPM scores. For those outcomes, floor effects were less pronounced than in the case of maths and literacy and their distribution was more evenly distributed across the full range of cognitive abilities. This is likely due to the fact that both tests measured cognitive abilities, not schooling achievement (see, Supplementary Figure G2, and for disaggregation of test scores by gender, place of residence, and poverty, Appendix H).

[FIGURE 3 ABOUT HERE]

Finally, it is worth noting that the autocorrelations of test scores between baseline and follow-up were low by the standards usually adopted in the literature\(^\text{11}\) (maths: \(\rho = 0.23\); literacy: \(\rho = 0.31\); digit: \(\rho = 0.19\); raven: \(\rho = 0.13\), all significant at \(< 0.01\)). Beyond some degree of measurement error, this may be due to the three-year lag between the two survey rounds.

\(^{11}\) McKenzie (2012), for instance, posits that low autocorrelation ranges between \(\rho = 0.2\) to 0.4.
### 3.6 Identification

We assessed program impact through an ITT approach by comparing test scores between eligible children that were in communities randomly assigned to the school feeding program or the control. The ITT parameter represents the average effect of offering school feeding to children that were eligible to the program at baseline in treatment communities, regardless of whether they actually had school lunches at endline. Given the imperfect program uptake and the implementation issues documented in Section 3.3, ITT parameters may likely represent a lower bound for potential program effects. The estimated parameters are of policy relevance because program offering can only partially influence uptake or other behaviors at the household level such as within-household food redistribution.

In the analysis plan (Gelli et al. 2016), we outlined two potential strategies to estimate the ITT parameters, depending on different outcomes of interest: ANCOVA and difference-in-differences (DiD). The former improves statistical power by conditioning the endline outcome on the assignment to treatment and the baseline value of the outcome. Following McKenzie (2012) and Frison and Pocock (1992), this is our preferred estimator due to its greater efficiency (defined as retaining unbiasedness with lower variance) in estimating average treatment effects with experimental data, as compared to both the post-estimator and the DiD approach. Gains in efficiency are particularly marked when outcomes have low autocorrelation, as in our case. In econometric terms, we estimate the following model:

\[
y_{it,j} = \alpha_{it,j} + \beta_1 S_{it,j} + \beta_2 y_{i(t-1),j} + \theta_j + \epsilon_{it,j} \quad (1),
\]

Where \( y_{it,j} \) and \( y_{i(t-1),j} \) represent, respectively, the endline and baseline test scores (when available)\(^{12}\) for child \( i \) residing in community \( j \); \( S_{it,j} \) is a dichotomous variable for a child residing in a community randomly assigned to school feeding and thus uncorrelated with \( y_{i(t-1),j} \); and \( \theta_j \) is a vector of region dummies to capture region-specific unobservable characteristics or potential variation in quality of implementation. Standard errors were clustered at the community level, which is the unit of randomisation for school feeding. \( \beta_1 \), the

---

\(^{12}\) Results are unchanged when a dummy variable for missing baseline test score is included.
coefficient related to school feeding, provides the estimate of the treatment effects. For completeness with the analysis plan, we also provide DiD coefficients in Appendix I.

4 Impact of School Feeding on Educational Attainments

Table 4, Panel A presents ITT estimates for the full sample. Overall, the randomized offer of school feeding led to significant increases across all test scores of about 0.12 to 0.15 $\delta$. We then investigate whether the effect of the offer of school feeding varied by child gender, household socioeconomic status, and place of residence. Table 4, Panels B, C, and D, respectively, report treatment effects in models that stratify for gender, poverty, and northern regions. Across the three subgroups, school feeding led to sizeable gains in achievements. In the case of girls, literacy and digit span scores increased by 0.2$\delta$ and maths by 0.24$\delta$ (Panel B). The composite scores also increased by more than 0.2$\delta$.

Even larger gains were evident in the case of children from households below the poverty line at baseline (Panel C) and children from northern Ghana (Panel D). For the former, gains in maths scores and in the three composite scores amounted to a third of standard deviation, while the increases in literacy, SPM, and Digit Span were slightly smaller, but still accounting to more than 0.2$\delta$. A similar picture emerges from the findings related to northern regions children.

[TABLE 4. Main effects and gender, poverty and northern regions]

We also investigated variation in treatment effects by age in Appendix J. The latter shows that the effect of school feeding was mostly similar, with the exception of maths, between children of different age groups at baseline. However, in the younger cohort (children that were aged 6-11 years at baseline), effects were more precisely estimated, probably due to larger sample sizes. Finally, although it was not part of the analysis plan, we investigated variation by treatment modality in Appendix K. No substantial differences in treatment effects on educational achievements between the two programs were detectable.

13 While the treatment effects arising from both ANCOVA and DiD are in most cases remarkably similar, as anticipated, the former estimator proved being more efficient compared to DiD (Appendix G).
5 Mechanisms

This section investigates the role of changes in school participation and child time use as potential mechanisms explaining program effects. Descriptive statistics of all intermediate outcomes are presented in Appendix L.

5.1 Changes in Schooling

We start by changes in schooling following the intervention, as increases in school enrolment and attendance constitute critical pathways for learning. Also, if school feeding was successful in increasing learning, we should be able to observe higher grade attainments and lower grade repetition rates. Table 5 presents ITT estimates of school feeding on the following indicators: child school enrolment in any educational level; school enrolment in primary school; school attendance (conditional on enrolment), as measured by the number of days the child attended school out of a five-day week; current grade attended by the child; and a dichotomous variable related to whether a child has ever repeated a grade. All of these variables were measured in the household survey with questions directed to the child or her caregiver in both survey rounds.

Panel A reports estimates of school feeding for the full sample. Given the observed heterogeneity in treatment effects by specific population subgroups, Panel B, C, and D report ITT effects for girls, children from poor households, and children from northern regions, respectively.

Increases in school enrolment emerge as an important channel for impact, but only for the most disadvantaged groups. Given the almost universal rates of primary school enrolment in the country, the gains in access were mostly driven by children at the margin (girls, poor, and northern-region children). This finding is expected in contexts such as Ghana, where primary enrolment is almost universal, and the largest gains in school access are now to be among groups that are more likely to be out of school. Consistently with the results on learning and increases in enrolment, there were increases in grade attainment. Estimates were positive for all groups,

\[14\] Detailed effects on child anthropometrics are reported in a companion paper.

\[15\] DiD results are consistent to ANCOVA, and available upon request.
but they were only statistically significant for the average child and for children from the northern regions, indicating that children in school feeding areas completed more years of schooling than control.

Finally, there was no evidence of increased repetition in the school feeding arm. This result reassures about potential concerns of children not progressing to secondary school in order to continue receiving free meals, as observed in other SSA settings (Kazianga, De Walque, and Alderman 2012).

[TABLE 5 HERE]

5.2 Changes in Time Use

Table 6 provides ITT effects on child time use for the full sample (Panel A), stratified by child gender, household poverty, and northern regions (Panels B, C, and D, respectively). The indicators measured the average time (in hours), on a typical day, a child spends in the following activities: at school; studying; doing housework; doing farm work or other types of labor; and in leisure. These questions were only collected at endline, therefore treatment effects were estimated through a post-estimator.

While there were no significant changes in time use for the average child, there were increases in the time spent in school for all vulnerable subgroups. The increase in time spent in school ranged from about 30 additional minutes per day for girls, up to 50 additional minutes per day for children from poor households. Given that the average serving time for school feeding is about 30 minutes, it is plausible that the additional net time spent in school in the case of poor children is employed in instructional activities, and thus constitute a potential pathway to increased test scores. Qualitative evidence from field visits and focus group discussions conducted as part of this evaluation highlighted that children in school feeding communities tended to stay at school in the afternoon, while otherwise they would have not returned to school after having lunch at home (Fernandes et al. 2017). Also, teachers qualitatively reported extending the instructional time by about 45 minutes in the afternoon to accommodate the time lost earlier in the day due to the serving and eating of the meals. Similar increases in time spent in school during the afternoon shift due to school feeding were observed in Northern Uganda (Alderman, Gilligan, and Lehrer 2012).
For children from the household below the poverty line, there was also a significant decrease in time spent in housework, with a decrease of about 20 minutes per day. We speculate that the indirect income transfer from school feeding has led poorest households, which usually tend to rely more on children for household chores and care, to forego part of the benefits stemming from children’s housework in favor of additional schooling time. An analogous finding was reported for rural Burkina Faso, where school feeding led to shifts from farm labor to housework, which may be more compatible with school attendance (Kazianga, De Walque, and Alderman 2012).

6 Some Cost Considerations

The provision of a full cost-benefit/cost-effectiveness analysis of the GSFP is beyond the remit of this paper, especially given that the program is meant to affect a wide set of outcomes (education, health, social protection, agriculture), which should be assessed jointly to provide an accurate measure of cost-effectiveness (Gelli et al. 2014). Also, even if we would decide to restrict the focus on educational achievements as single measure of outcomes, this exercise may be still unsatisfactory, as the life course and intergenerational effects of gains from increased schooling achievements are not yet fully known\(^\text{16}\).

While we leave these important issues for future research, back-of-the-envelope calculations based on the Government of Ghana’s transfer to caterers and an average of 200 school-days per year suggest that the program costed about US$66 per child per year in 2015/16\(^\text{17}\). This figure falls within the range of the average cost per child of school meals in LMICs: the latest data available highlight that in 2008, school feeding cost US$54 and US$83 in low- and middle-income countries, respectively (Gelli and Darayani 2013). Taking inflation into account\(^\text{18}\),

\(^{16}\) For instance, in the context of Ghana, Duflo et al. (2017) have recently assessed the medium-term effects of secondary school scholarships. After eight years, scholarship winners had higher schooling, scored on average 0.15 greater in maths and literacy, had better health behaviors, and girls had less children.

\(^{17}\) This is a very rough estimation as it does not include full implementation costs (e.g., other costs at the school-level that are not included in the government budget for school feeding).

\(^{18}\) For instance, Gelli and Darayani show that between 2005 and 2008, the costs of school feeding increased by 12 percent and 24 percent, on average, in middle- and low-income countries, respectively.
the GSFP compares well with other programs in LMICs in terms of costs. Also, it is worth noting that most available estimations of program costs are based on WFP operating costs. As the WFP is the largest school feeding implementer in the world and operates through a centralized model that allows economies of scale, its cost estimates likely provide a lower bound for government programs. This is especially relevant for countries seeking food procurement within national boundaries using “home-grown” approaches, such as Ghana, in order to stimulate internal agricultural production and rural poverty reduction, at the potential cost of raising programmatic budgets through the purchase of higher-cost, locally-grown staples.

7 Concluding Remarks

Most governments globally offer some form of food at school as a large-scale strategy to improve children’s education and health. Given the pervasiveness of school meals programs worldwide and size of global educational investments in such intervention, understanding whether large-scale, government-led school feeding is effective in raising achievements, and whether it works for marginalized groups of learners, is a critical policy question and evidence gap.

We report treatment effects estimates from a randomized control trial focusing on a program reaching daily two million children across the poorest districts of Ghana. Program impacts were evaluated after two academic years of implementation in randomized communities across learning and cognitive attainments. We show that the offer of school feeding in randomized communities led to moderate gains in learning and cognitive levels for the average pupil. The magnitude of the effects (about 0.15δ) was comparable to estimates from a recent meta-analysis of school feeding (Snilstveit et al. 2015). Beyond average effects, the program had remarkable impact among the groups that are more marginalized learners in Ghana. For girls, children from poor households and children residing in the country’s northern regions, school feeding led to dramatic improvements in learning and cognition – ranging between 0.2δ to 0.3δ. All estimates are likely to represent lower bounds due to imperfect uptake. The positive effects on learning and cognition are especially remarkable when contextualized to the implementation challenges related to the delayed disbursements to the caterers. Regularity in the provision of
school meals and their quality is in fact critical for the effectiveness of the program, as children and parents may respond to irregular or lower quality meal provision in multiple ways (e.g. going home for lunch and not returning to school afterwards, changing school type or not attending at all). Overall, the noted challenges add to the generalizability of our findings to large-scale, government-led school feeding interventions implemented in similar contexts, which may face financial, implementation, and monitoring constraints.

To the best of our knowledge, this is the first study providing experimental evidence on a government’s school feeding program implemented nationwide in a LMIC, with an investigation of the effects of the intervention for most vulnerable learners and impact mechanisms. So far, only a few studies have focused on the impact of national school meals programs on learning using quasi-experimental methods. In India, a growing literature has documented that the local “Midday-Meal” scheme has improved learning and cognition (Afridi, Barooah, and Somanathan 2016; Chakraborty and Jayaraman 2016). Chakraborty and Jayaraman (2016) exploited staggered program implementation across Indian States to estimate effects on literacy of about 0.18δ and on maths of 0.09δ. Recently, two trials have used the infrastructure of the Indian school feeding program to scale up food fortification, with mixed effects on learning (Berry et al. 2018; Krämer, Kumar, and Vollmer 2018). In Chile, a middle-income country with little undernutrition, McEwan (2013) applied a regression discontinuity design to administrative data, without finding any impacts of the local school meal program on fourth-grade test scores. Belot and James (2011) evaluated the educational effects of improvements in the quality of school meals in a borough of London by employing difference-in-difference. They found evidence of improved English and science scores and decreases in absenteeism due to sickness.

Of importance, especially for children at the margin, school feeding positively affected educational achievements through promoting increases in school participation and shifts in time use from housework to increased school participation. The offer of school feeding led to increased enrolment rates for all children, with larger impacts for children of poorest families and regions, increases in time spent at school (presumably beyond the meal serving time among the

---

19 These effects are not directly comparable to our estimates, given differences in the tests administered and in dispersion of achievements across populations.
poorest children), and increases in grade attainments. School feeding, by subsiding the cost of schooling and providing an indirect income transfer to the household, promoted enrolment, grade attainment and increase in time spent in activities that are more compatible with learning. In the SSA context, such reduction in the cost of education may be particularly effective in raising the educational outcomes of vulnerable population segments (Aurino et al. 2018; Björkman-Nyqvist 2013; Kazianga, de Walque, and Alderman 2012). Further, findings from a companion paper highlight gains in anthropometric status among girls, children from poor households and northern regions, which highlight the effectiveness of the program among the most disadvantaged groups (Gelli et al., 2018).

Contextualized to Ghana, these findings address concerns raised in a 2010 Ministerial review of GSFP, according to which program investments targeted disproportionately better-off districts (Balwanz and Darvas 2013; WFP 2013). Based on our results, it appears that the retargeting of the program to the country’s most food-insecure districts had been able to address potential concerns of regressivity.

Overall, our findings highlight the role of government-led school feeding programs as a social protection tool with positive and equitable impacts on human capital accumulation, particularly for marginalized groups of learners. Increasing average learning levels by narrowing the gaps in the distribution of achievements is critical for sustainable growth. Therefore, this evidence shows that government-led school feeding programs can be an important policy tool for attaining the 2030 sustainable development agenda, which will contribute towards provision of a more educated and productive workforce in resource-constrained settings.

Notes: *** p<0.01, ** p<0.05, * p<0.1. This table presents odd ratios of remaining in the longitudinal sample estimated through logistic regression models, with standard errors clustered at the community level. All models include probability of Wald Chi-squared test of joint significance of all regressors. N= 3,433 children of target-age prior to attrition. Lower sample sizes reflect covariates that are missing or not applicable. Column 1 shows odd ratios of child being followed-up by treatment assignment; column 2 presents odd ratios by baseline learning and cognition, while column 3 interacts randomized assignment with key variables by which heterogeneity analysis was conducted throughout the paper. Household poverty is a dichotomous indicator having the value of one if the household had baseline per capita consumption levels falling below the national consumption poverty line in 2013. Northern regions include Upper West, Upper East, and Northern region. Southern regions include Western, Central, Greater Accra, Volta, Eastern, Asanti, Brong Ahafo.

\(^a\) The school feeding-control difference column reports the school feeding coefficient of a basic OLS regression of each outcome over school feeding arm and controlling for child age in months. Standard errors are clustered at the community level. SPM stands for standardised progressive matrices test. Lower sample sizes in the cognitive scores (as compared to the full longitudinal sample) reflect missing values in those scores.

Notes: *** p<0.01, ** p<0.05, * p<0.1. The table above presents intent-to-treat effects on each outcome for the full sample and stratified by child gender, household poverty, and northern regions. Models were estimated through OLS and standard errors were clustered at the community level. For each outcome, the model controls for the baseline value of the outcome, a dichotomous variable related to the randomized assignment to school feeding, and region dummies. Maths, literacy, standardized progressive matrices (SPM) and digit span scores are age-standardized. Composite indices were computed as averages of the standardized scores and then they were standardized to the control group within each round. Household poverty is a dichotomous indicator having the value of one if the household had baseline per capita consumption levels falling below the national consumption poverty line in 2013. Northern regions include Upper West, Upper East, and Northern region. Southern regions include Western, Central, Greater Accra, Volta, Eastern, Asanti, Brong Ahafo.

Notes: *** p<0.01, ** p<0.05, * p<0.1. The table above presents intent-to-treat effects on each outcome for the full sample and stratified by child gender, household poverty, and northern regions. Models were estimated through OLS and standard errors were clustered at the community level. For each outcome, the model controls for the baseline value of the outcome, a dichotomous variable related to the randomized assignment to school feeding, a dichotomous variable for missing baseline outcome, and region dummies. Enrolment is a dichotomous variable indicating whether the child is enrolled to any level of education; attendance is an indicator counting the number of days the child attended by the child in the past school week. The indicator ranges from 0 to 5 days. Current grade provides the educational grade (in years) the child is currently enrolled in. Grade repetition is a dichotomous variable of whether the child has ever repeated a grade. Household poverty and northern regions are defined in note below Table 5.

</table>

Notes: *** $p<0.01$, ** $p<0.05$, * $p<0.1$. The table above presents intent-to-treat effects on each outcome for the full sample and stratified by child gender, household poverty, and northern regions. Models were estimated through OLS with region dummies and standard errors were clustered at the community level. Time spent in school is an indicator that measures the average time (in hours) a child spends in school on a typical week day (in the school term); time spent in study is an indicator that measures the average time (in hours) a child spends studying at home or taking private tuition on a typical day; time spent in household chores is an indicator that measures the average time (in hours) a child spends doing household chores or care for other household members on a typical day; time in work is an indicator that measures the amount of time a child spends working in agriculture work, in the family business, or in another work activity on a typical day; leisure time measures the average amount of play and other leisure activities on a typical day. Household poverty and northern regions are defined in note below Table 5.
Figure 1. Two-level randomisation

Notes: this figure provides the study design: first, districts were randomly assigned to pilot (HGSF) and standard (GSFP) school feeding through a first-level randomization; second, within each district, two schools (and related households living within the school catchment areas, which were refer to as “communities”) were randomly assigned to school feeding or control. Note that due to the discovery of the GSFP already present in 25 communities at baseline, these were dropped from the original community sample. Two additional communities could not be resurveyed due to local violence at the time of the endline survey. An original third level of randomization was dropped soon after the baseline due to substantial delays in implementation and the limited number of schools still available after the removal of schools that we discovered had school feeding at baseline.
Figure 2. Empirical distributions of raw test scores for maths (left-side panel) and literacy (right-side panel), by survey round and treatment arm

Notes: this figure presents, by treatment group and survey wave, the non-parametric distributions of maths (left-side panel) and literacy (right-side panel) raw scores for the full longitudinal sample of children. Non-parametric distributions were calculated through weighted local polynomial regressions using an Epanechnikov kernel. These data are from the household survey, and therefore do not suffer from selection issues related to school enrolment. Floor effects were present, particularly in the baseline data; highlighting the tests were too difficult, particularly for the younger children. Second, there was an improvement in mean achievement in both competences between baseline and endline, although achievements were widely dispersed across the sample. Third, the distribution of achievements, especially in literacy, of the school feeding group appeared to be above the one of control at endline across the mid- to upper-end of the distribution of achievements.
Figure 3. Empirical distributions of raw test scores for Digit Span (left-side panel) and SPM (right-side panel), by survey round and treatment arm

Notes: this figure presents, by treatment group and survey wave, the non-parametric distributions of digit span (left-side panel) and standardized progressive matrices (SPM) (right-side panel) raw scores for the full longitudinal sample of children. Non-parametric distributions were calculated through weighted local polynomial regressions using an Epanechnikov kernel. Some floor effects were present, particularly in the baseline data. Second, a decrease in SPM test scores was evident for both treatment and control groups at endline. This was mostly driven by the older cohort of children.
